Although the Java programming language has achieved widespread acceptance, what seems sorely missed is the ability to use type parameters (as in Ada, C++, Eiffel, and ML polymorphic functions or data types) to allow a generic class to be instantiated to one or more specific types. In this paper, we propose parameterized classes and interfaces in which the type parameter may be constrained to either implement an interface or extend a given class. This design allows t ...

The contribution of the paper is twofold. First, we define a general notion of principal typings equipped with an entailment relation between type environments; this generalization can be used as a pattern for instantiating type systems able to support separate compilation and inter-type checking of Java-like languages, and allows a formal definition of soundness and completeness of inter-checking w.r.t. global compilation. These properties are particularly useful in practice since they allow selective recompilation. In particular, the paper shows how to ...

This paper describes how to add first-class generic types---including mix typed OO languages with nominal subtyping such as Java and C#. A generic is "first-class" if generic types can appear in any context where conventional types can appear. In this context, a mixin is simply a generic class that extends one of its type parameters, such as a class $C<T>$ that extends T . Although mixins of this form are widely used in Java (and in C++ templates), they are clumsy and error-prone.

This paper describes a type system that is capable of expressing and enforcing immutability constraints. The specific constraint expressed is that the abstract state of an immutable reference refers to an immutable object. The type system permits the expression of constraints on the abstract state of an object that is part of the transitively reachable state: that is, the state of the object and all objects that can be reached from it by following references. The type system permits explicitly excluding the abstract state of an object from the transitive reachability of an object.

Events are a better means of managing I/O concurrency in server software. Events help avoid bugs caused by the unnecessary CPU concurrency introduced by threaded programs. We argue that our libasync non-blocking I/O library makes programming convenient and evaluate extensions to the library that allow programs to take advantage of multi-processors. We conclude that e ...

Redundancy alone is not sufficient to provide long-term guarantees in distributed systems. Instead, it must be coupled with mechanisms for automatic maintenance. In this paper, we show how Decentralized Object Location and Routing networks (DOLR) can provide a framework for efficient heartbeats and continuous system repair.

With large-scale embedded systems, improvement of development efficiency is one of the most important problems. In this paper, we design and implement an embedded system, called the Lambda operating system, which improves the maintainability and efficiency of the development process.

development efficiency of the operating system. The Lambda operating system has a micro-kernel architecture, which allows the operating system to be easily modified. In addition, we propose a method to improve operating system performance.

Modern database systems provide not only powerful data models but also languages supporting powerful features such as the ability to create new and invocation of arbitrary methods (possibly written in a third-party programming language). In this sense query languages have evolved into powerful programming languages. Surprisingly little work exists utilizing techniques from program research to specify and analyse these query languages. This paper provides

As the articles in this section attest, the future of Web services is as certain as ever. That is, the Web services arena is most certainly the next technological vanguard. Microsoft has developed a language called C# ("see sharp") that it claims to make it easier for programmers to "quickly and easily build solutions" for its new .NET platform. The language has much in common with Java, particularly in those features emphasized in CS1 and CS2 courses. It also includes some of the desirable features of C++ that are not available from Java as well as some new features not available in either language. The paper discusses the pros and cons of teaching CS1 and CS2 using C# instead of Java.

Frameworks and domain-specific visual languages are two different reuse approaches. The first is targeted at expert programmers, the second at domain experts. In fact, they are closely related. This paper shows how to develop a domain-specific language by first developing a white-box framework for the domain, then turning it into a domain-specific language framework, and finally building a graphical front end for it. We used this approach to build a compiler to specify run-time systems.

The object-oriented style of programming facilitates program adaptation and reuse, but at the expense of efficiency. We demonstrate experimentally that state-of-the-art Java compilers fail to compensate for the use of object-oriented features in the implementation of generic programs, and that program specialization can significantly reduce these overheads. We present an automatic program specialization tool for Java, illustrate its use through detailed case studies, and discuss its performance.
